Outline

- > Traditional machine learning vs. deep learning
- > Gradient decent
- > Neural networks
- > Deep neural networks
- > Convolutional neural networks (CNN)
- > Layers, pooling, and activation
- > AlexNet, VGG, and ResNet

Traditional classification methods work well for simple tasks. Models are usually built in a controlled environment (e.g., lab setting) to eliminate the variations of illumination, viewpoints, scales, and so on.

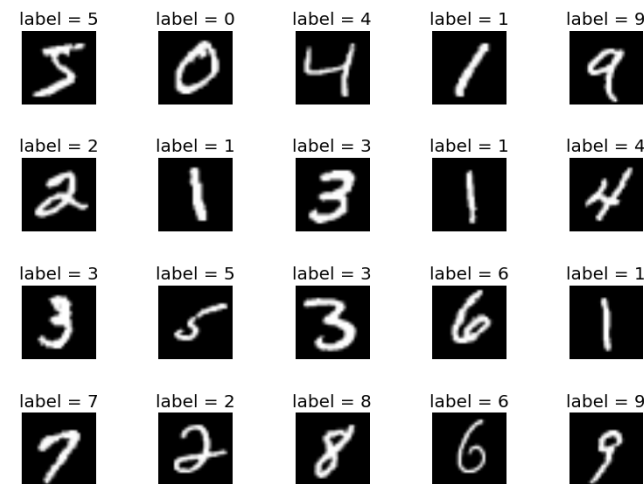

Popular traditional datasets

There are 40 distinct people in the dataset

Olivetti Face Dataset, AT&T

Popular traditional datasets

MINIST Handwritten Digits

Popular traditional datasets

Palmprint Acquisition and Datasets

However, in real applications,
those are inevitable.

Deep Learning is a popular solution to address these challenges.

(This is what you're waiting for. LOL!)

Let's start by reviewing the learning of decision boundary through an example – to classify the red and green apples.

List of apples

No.	x	y	others	Color (z)
1	9	53	...	Red (1)
2	25	45	...	Green (-1)
3	225	56.7	...	Red (1)
4	576	52.9	...	Green (-1)
5	676	60.2	...	Red (1)
6	900	55.7	...	Green (-1)
7

Apple Space

Apple Space

To find the best line
dividing the two groups
of apples is to find the
best **parameters** of **a**
and **b**

The line: $y = a*x + b$

Apple Space

To find the best line dividing the two groups of apples is to find the best **parameters** of **a** and **b**

The line: $y = \mathbf{a} * \mathbf{x} + \mathbf{b}$

The model:

$$z = \mathbf{a} * \mathbf{x} - y + \mathbf{b}$$

Outputs **1** if $z > 0$

Outputs **-1** if $z \leq 0$

Apple Space

To find the best line dividing the two groups of apples is to find the best **parameters** of **a** and **b**

The line: $y = a \cdot x + b$

Apple Space

Initialization

Without knowing which line is the best at the beginning, we can pick a random one by setting a and b with random numbers a' and b' .

Apple Space

Initialization

Without knowing which line is the best at the beginning, we can pick a random one by setting a and b with random numbers a' and b' .

The model:

$$z_0 = a' * x - y + b'$$

How can we evaluate how good the
model (**a'** and **b'**) is?

Intuitively, we can compare the
prediction **z'** to the **ground truth**
label **z** using **(z'-z)²**. By applying to
all **N** samples, we have a **loss**
function

$$L(a', b') = \frac{1}{N} \sum_{i=1}^N (z'_i - z_i)^2$$

With the “goodness” evaluated,
we can update a' and b' by
replacing them with better ones.

The updating process is so
called **learning**.

But, how?

The best parameters are the ones that minimize the loss function L . The optimal parameters can thus be found at where the **gradients** of L are zeros

$$\frac{\partial L}{\partial a} = 0, \frac{\partial L}{\partial b} = 0.$$

We can update a' and b' by pushing the gradients towards zeros!

$$a' = a' - \frac{\partial L}{\partial a'}$$

$$b' = b' - \frac{\partial L}{\partial b'}$$

Learning Rate

Gradient Decent

We can update a' and b' by pushing the gradients towards zeros!

$$a' = a' - \delta \frac{\partial L}{\partial a'}$$

$$b' = b' - \delta \frac{\partial L}{\partial b'}$$

Learning Rate

Gradient Decent

We can update a' and b' by pushing the gradients towards zeros!

$$a' = a' - \delta \frac{\partial L}{\partial a'}$$

$$b' = b' - \delta \frac{\partial L}{\partial b'}$$

Learning Rate

Apple Space

Machine learning is a process to find the best set of **parameters** that fits into a **model/hypothesis**. The learning is usually conducted by updating the initial parameters with a learning rate towards the optimal of a **loss function**. **Gradient Decent** is one of the most popular updating strategies.

Let's implement the learning using **neural networks**.

Neural Network Version of the Model

Neural Network Version of the Model

Neural Network Version of the Model

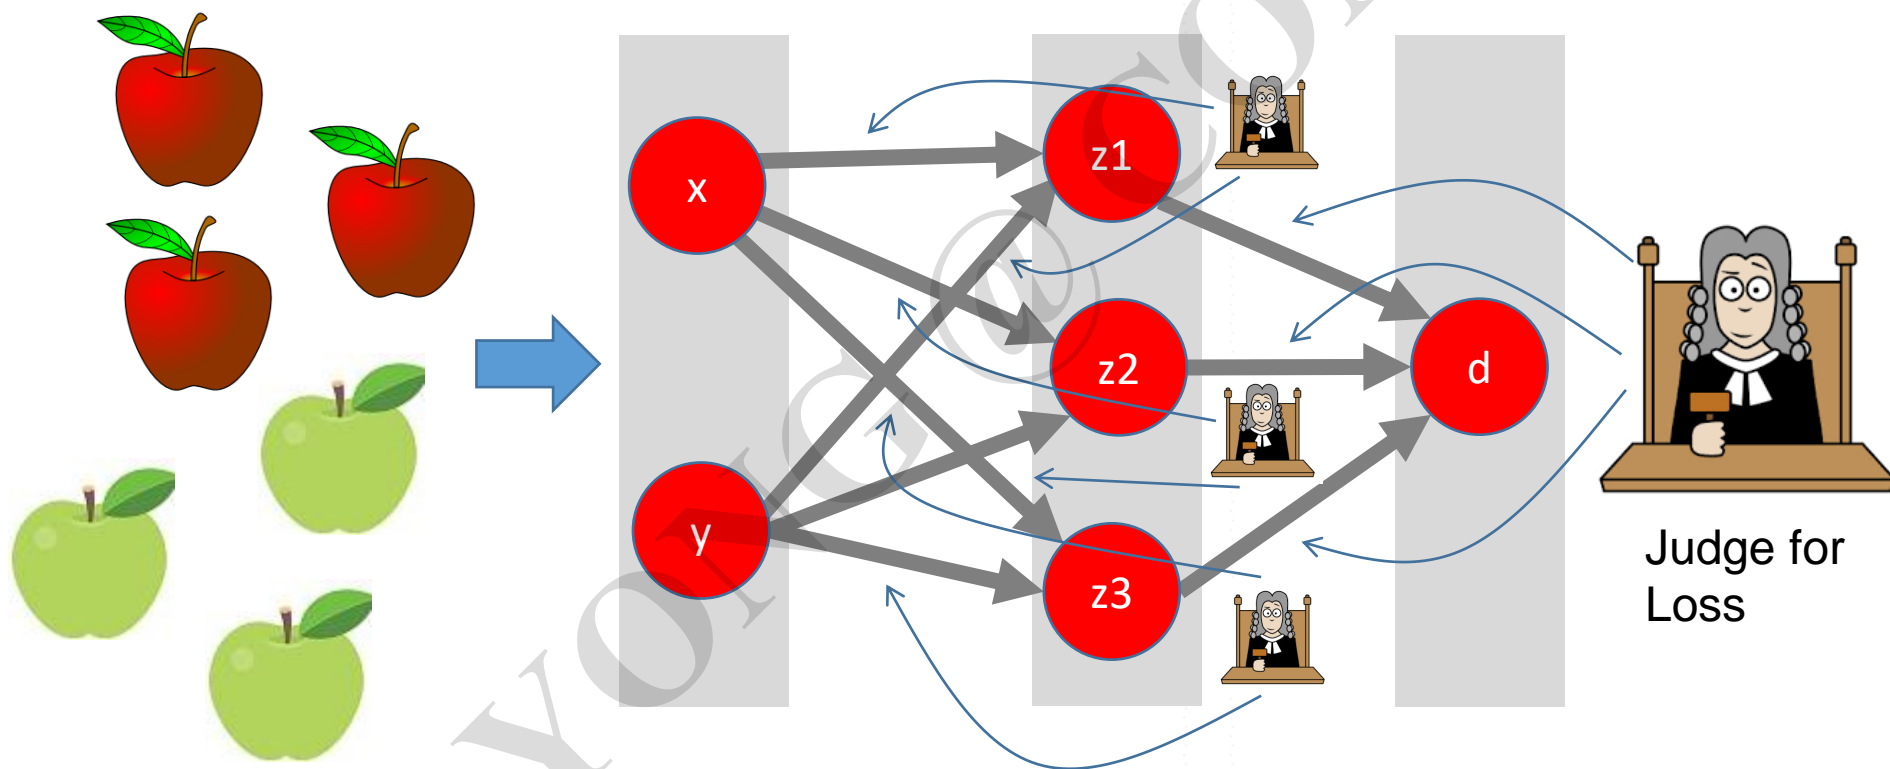

How is the learning conducted with more layers and weights?

Gradient Decent on Neural Networks

Gradient Decent on Neural Networks

The Chain Rule for Backpropagation

By stacking more layers you have Deep Neural Networks

By employing more loss judges you have **Deep Learning**

Now, we're ready for a few
more concepts (tricks)?

Layers

Input layer : Receive data from external sources (data files, images, sensors, etc.)

Hidden layers : process data

Output layer provides network-based functions for one or more data points

Convolutional Layers

Instead of using fully connected layers, we can add a few more “partially” connected layers.

Recall the Filters and Convolutions

$$G_x = \begin{bmatrix} 1 & 0 & -1 \\ 1 & 0 & -1 \\ 1 & 0 & -1 \end{bmatrix}$$

Prewitt filter for vertical edge detection

$$G_y = \begin{bmatrix} 1 & 1 & 1 \\ 0 & 0 & 0 \\ -1 & -1 & -1 \end{bmatrix}$$

Prewitt filter for horizontal edge detection

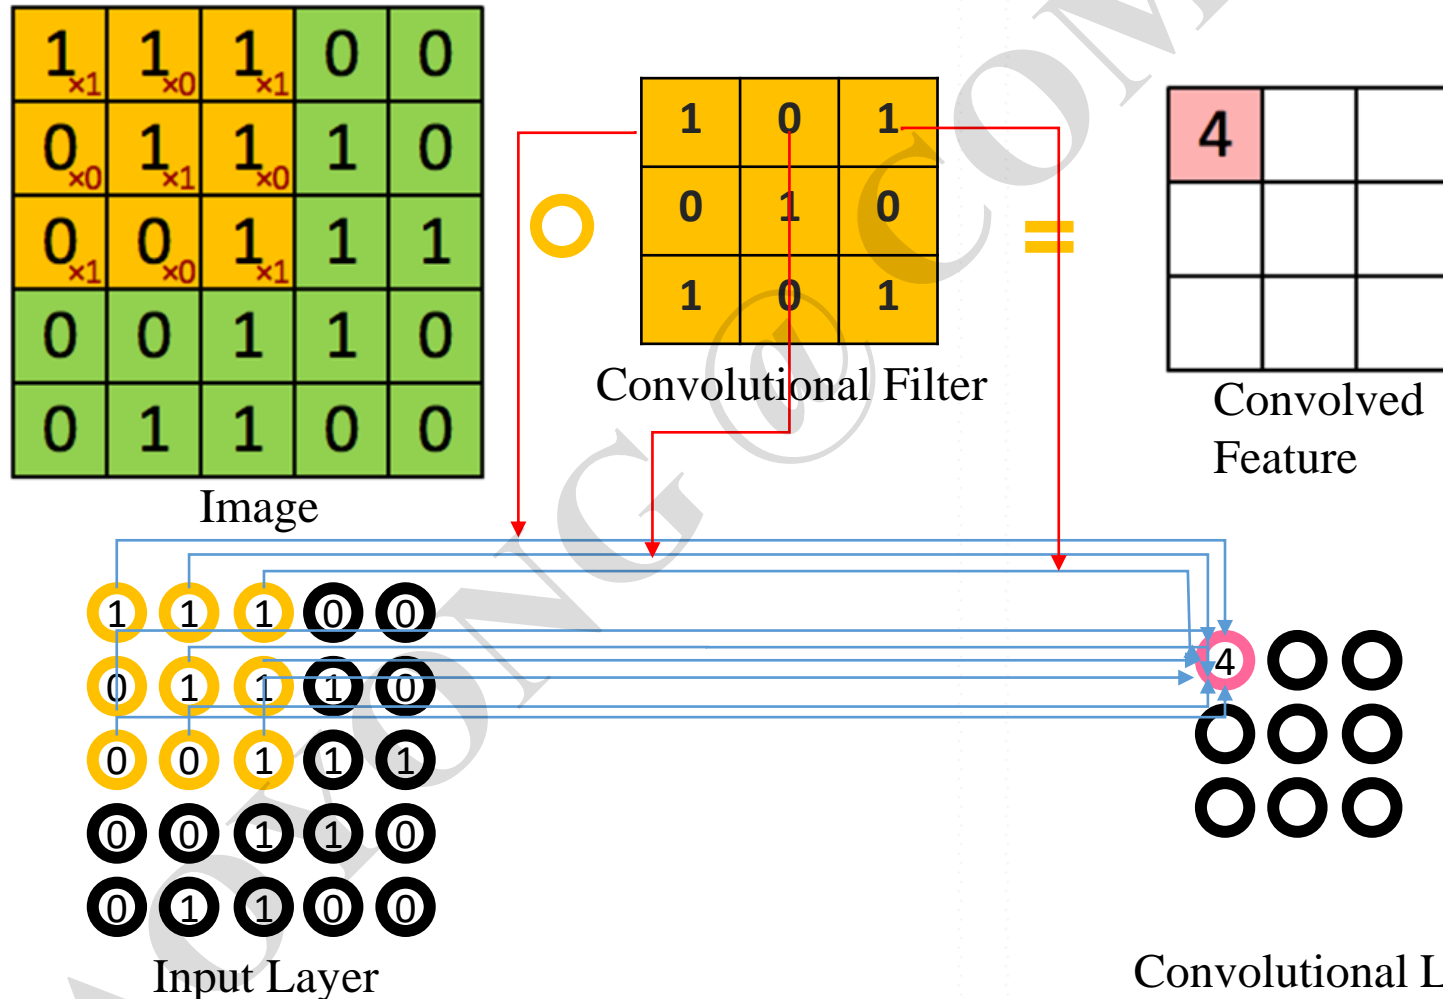

-1	0	1
-2	0	2
-1	0	1

Sauber Filter

Implement with Neural Networks

Implement with Neural Networks

Implement with Neural Networks

Weights of the filters can be learned by **Backpropagation**

1 _{x1}	1 _{x0}	1 _{x1}	0	0
0 _{x0}	1 _{x1}	1 _{x0}	1	0
0 _{x1}	0 _{x0}	1 _{x1}	1	1
0	0	1	1	0
0	1	1	0	0
